RECOMMENDATIONS

PREGNANCY AND HCV
- Clinicians should perform HCV screening in all patients who are pregnant or planning to get pregnant. (B3)
- Clinicians should advise pregnant patients with HCV to defer treatment with DAAUs until they are no longer pregnant or breastfeeding. (A2)
- If an individual with HCV becomes pregnant during DAA treatment, clinicians should (A3):
  - Advise that the use of DAAUs is not currently recommended during pregnancy because no data are currently available on the effects of medications on the fetus.
  - Discuss the risks and benefits of continuing treatment.
- Clinicians should refer pregnant patients who are diagnosed with HCV (HCV antibody and HCV RNA positive), or who are known to have HCV and become pregnant before or during DAA treatment, to a specialist experienced in counseling about HCV in pregnancy. (A3) Specialists may include, but are not limited to, hepatologists, gastroenterologists, infectious disease specialists, or high-risk obstetricians.
- If a pregnant patient with HCV has a substance use disorder, the clinician should provide substance use treatment, including harm reduction services, or refer the patient for these services. (A3)
- Clinicians should advise pregnant and postpartum individuals with HCV mono-infection that breastfeeding is considered safe, and HCV is not transmitted through breastmilk. (B3)
- Clinicians should advise patients that if they have or develop cracked or bleeding nipples, breastfeeding should be discontinued, and milk should be expressed and discarded until bleeding has resolved. (B3)
- Clinicians should refer infants born to mothers with HCV to clinicians with experience in HCV care for further counseling and testing and notify the clinician of the mother’s HCV status. (A3)

ACUTE HCV INFECTION
- Clinicians should suspect acute HCV infection if a patient who had a negative antibody test documented within the previous 6 months has a new positive antibody test or has detectable HCV RNA in the absence of a positive antibody test. (A3)
- Clinicians should not prescribe pre- or post-exposure prophylaxis to prevent HCV infection. (A1)
- Clinicians should screen all patients with possible acute HCV infection for HIV, HAV, and HBV infections, given the similar risk factors for acquisition. (A3)

PRE-TREATMENT ASSESSMENT
- Clinicians should assess all patients with a confirmed diagnosis of chronic HCV infection for treatment. (A1)
- Clinicians should obtain HCV genotype/subtype testing for all patients before starting treatment with DAAUs. (A1)

WHEN TO REFER TO A LIVER SPECIALIST
- Clinicians new to treating chronic HCV infection should consult with a liver disease specialist when treating chronic HCV infection in patients with any of the following conditions (A3):
  - Compensated or decompensated cirrhosis.
  - Concurrent hepatobiliary conditions.
  - Extrapancreatic manifestations of HCV, including renal, dermatologic, and rheumatologic manifestations.
  - Significant renal impairment (CrCl <30 mL/min) or who are undergoing hemodialysis.
  - Active HBV infection, defined as HBV surface antigen positive and detectable HBV DNA.
  - Pre- or post-transplant status.
- Clinicians new to treating chronic HCV infection should consult with a liver disease specialist when evaluating patients for retreatment after any DAA treatment failure. (B3)

REPORTING
New York State Public Health law mandates that clinicians report all suspected or confirmed cases of HCV infection, specifying acute or chronic, to the local health department of the area where the patient resides.

MONTHLY PRINTED GUIDE

HCV POCKET GUIDE 1: DIAGNOSIS AND PRE-TREATMENT ASSESSMENT

NYSDOH AIDS INSTITUTE CLINICAL GUIDELINES PROGRAM

JUNE 2019
CHECKLIST: PRE-DAA ASSESSMENT

MEDICAL HISTORY

☐ Previous HCV treatment guides choice and duration of therapy.
☐ History of hepatic decompensation warrants referral to a liver disease specialist.
☐ History of renal disease may influence choice of regimen.
☐ Medication history and current medications, including OTC and herbal products, may guide choice of DAA therapy.
☐ Pregnancy status and plans: 1) HCV treatment is deferred during pregnancy; 2) Birth control use is essential during HCV treatment and for 6 months after treatment if patients are receiving RBV.
☐ HIV infection: 1) If HIV infection is confirmed, offer the patient ART; 2) If the patient is being treated with ARVs, assess potential drug–drug interactions; 3) Presence of HIV infection may influence fibrosis assessment modality, choice of treatment, duration, and monitoring.

☐ History of infection and vaccination status:
  - HAV: Obtain HAV antibody (IgG or total).
  - HBV: Obtain HBsAg, anti–HBs, and anti–HBe (total).
  - Administer PPSV23 vaccine to all patients with cirrhosis, which is associated with increased susceptibility to bacterial infections.
    - As indicated by the CDC/ACIP Recommended Immunization Schedule for Adults Aged 19 Years and Older.
  - Annual influenza vaccine.

PHYSICAL EXAM

☐ Presence of signs that suggest cirrhosis or decompensated cirrhosis may require additional evaluation and management or treatment: ankle edema, abdominal veins, jaundice, palmar erythema, gynecomastia, spider telangiectasia, ascites, encephalopathy, asterixis.

☐ Presence of signs related to extrahepatic manifestations of HCV, such as porphyria cutanea tarda, vasculitis, or lichen planus, may increase urgency of HCV treatment and may require additional evaluation and treatment needs.

☐ Liver size by palpation or auscultation for hepatomegaly or splenomegaly, as well as tenderness or hepatic bruits, may suggest severity of liver disease and may require additional evaluation.

LABORATORY TESTING

☐ HCV RNA quantification confirms active HCV infection and determines HCV viral load.
☐ Genotype/subtype guides choice of regimen.
☐ CBC: Low platelets (<140,000 platelets/μL) suggest cirrhosis and portal hypertension; anemia may necessitate choice of a regimen that does not contain RBV.
☐ Serum electrolytes with creatinine: Marked electrolyte abnormalities may suggest decompensated cirrhosis (e.g., hyponatremia); renal function will influence choice of regimen.

☐ Hepatic function panel: Elevated direct bilirubin suggests decompensated cirrhosis; markedly elevated transaminases may suggest comorbidities.

☐ INR: Elevated results suggest decompensated cirrhosis.
☐ Pregnancy test for all individuals of childbearing potential. If pregnant, suggest treatment deferral.
☐ HAV antibodies (IgG or total): Administer the full HAV vaccine series in patients not immune to HAV.
☐ HBV antibodies (HBsAg, anti–HBs, and anti–HBe [total]): Administer the HBV vaccine series (0, 1, and 6 months) to HBV-susceptible patients (negative for all serologies).
  - In patients with positive HBsAg, perform HBV DNA testing to assess for active HBV infection.
  - If HBV DNA is detectable, care providers new to HCV treatment should consult a liver disease or viral hepatitis specialist regarding treatment for HBV and HCV.
☐ HIV test if status is unknown.
☐ Urinalysis: Protein may suggest extrahepatic manifestation of HCV.
☐ Fibrosis serum markers: Obtain if not previously evaluated by biopsy or FibroScan.

Link to Care

Additional Testing as Appropriate†

HCV RNA testing if the person tested is suspected to have had HCV exposure within the past 6 months or has clinical evidence of HCV disease, or if there is concern regarding the handling or storage of the test specimen.

* For people who might have been exposed to HCV within the past 6 months, testing for HCV RNA or follow-up testing for HCV antibody is recommended. For people who are immunocompromised, testing for HCV RNA can be considered.
† To differentiate past, resolved HCV infection from biologic false positivity for HCV antibody, testing with another HCV antibody assay can be considered. Repeat HCV RNA testing if the person tested is suspected to have had HCV exposure within the past 6 months or has clinical evidence of HCV disease, or if there is concern regarding the handling or storage of the test specimen.
